## **Abstract**

This paper examines relationships between producer concentration, firm ownership, and employee compensation in Vietnam's manufacturing enterprises in 2000, 2002, and 2004. Simple calculations indicate that multinational corporations (MNCs) paid the highest compensation followed by state-owned enterprises (SOEs) and finally by private firms. After controlling for the effects of producer concentration and other technical determinants of compensation levels (e.g., factor intensity, scale, labor quality), compensation differentials are greatly reduced. MNCs still paid an average of about one-third to one-half more than private firms while SOE-private differentials became very small or negative. These differentials varied markedly among industry groups, however. The relationship between producer concentration and compensation levels was usually positive in samples of all manufacturing firms but negative in about half of the eight industry groups examined. Cross section estimates also indicate that larger MNC and SOE presence was associated with higher compensation in private firms in 2002 and 2004, suggesting positive spillovers from both SOEs and MNCs in these two years. However, fixed effects panel estimates, which examine the question of how SOE and MNC presence affected changes in private firm compensation over time, suggest that compensation in private firms tended to fall relatively rapidly in industries where SOE presence was large and producer concentration high, while MNC presence had no significant effect.

**Acknowledgement:** This study was partially funded by Japan Society for the Promotion of Sciences grant #18530224, which was given to Eric D. Ramstetter of the International Centre for the Study of East Asian Development for the purpose of coordinating the project "Market Structure and Firm Behavior in East Asia's Developing Economies". We are grateful for comments and advice from Fredrik Sjöholm, Sadayuki Takii, and Chih-Hai Yang.

## **1. Introduction**

There is a growing literature indicating that multinational corporations (MNCs) tend to pay higher wages or total compensation than local firms or plants in developing economies such as Indonesia (Lipsey and Sjöholm 2004a, 2006), Thailand (Ramstetter 2004; Matsuoka-Movshuk and Movshuk 2006), as well as Mexico and Venezuela (Aitken et al 1996). State-owned enterprises (SOEs) have also played a very important role in Vietnam and activity by locally-owned private firms has grown exceedingly rapidly since the implementation of the initial Enterprise Law in 2000. Vietnam is also a transition economy with laws and regulations which have forced MNCs and SOEs to pay relatively high wages both before and after the Enterprise Law's enactment. However, ownership patterns are changing rapidly and characteristics of MNCs and SOEs differ markedly from those of private firms. It is thus of interest to analyze the extent of compensation differentials among ownership groups to Vietnam and their relationships to other firm-level characteristics thought to affect compensation levels. These analyses have recently become feasible using firm-level data from Vietnam's recent enterprise surveys and the first purpose of this paper is thus to examine the nature of wage differentials among MNCs, SOEs, and private firms in Vietnam's manufacturing industries and how they have changed since the implementation of the Enterprise Law.

The aforementioned studies of Indonesia and Thailand also found that wages in local plants wages tended to be positively related to the extent of MNC presence in an industry. In other words, they found evidence of positive wage spillovers, in addition to wage differentials. Similarly, the second purpose of this paper is also to investigate whether the degree of MNC or SOE presence in

Vietnam's manufacturing industries is related to the wage levels in private firms.

Partially as a result of the large changes in Vietnam's enterprise landscape in recent years, there has also been a marked reduction in producer concentration in many manufacturing industries after 2000. Correspondingly, the third purpose of this paper is to highlight relationships between the level of producer concentration and compensation differentials or spillovers. The paper also highlights how the relationship between compensation levels and concentration differs among industry groups.

This paper begins with a brief review of the literature analyzing wage differentials among groups of firms (Section 2). This section also emphasizes how ownership-related wage differentials are reinforced by labor policies in the Vietnamese case. The paper then describes the data in some detail while reviewing the patterns observed in wage and compensation differentials, ownership shares, and related variables (Section 3). Analyses of compensation differentials (Section 4) and compensation spillovers (Section 5) are then performed after accounting for the influences of other firm- and industry-characteristics thought to affect compensation levels. As indicated above, particular attention is devoted to analyzing the relationship between the extent of producer concentration in an industry and compensation levels. Finally, some concluding remarks are offered (Section 6).

## **2. Wage Differentials, Ownership, and Spillovers**

The aforementioned studies of manufacturing plants in Indonesia (Lipsey and Sjöholm 2004a, 2004b, 2006) are perhaps the most sophisticated studies of wage differentials and spillovers available

because they were able to account for the influences of labor quality in some detail, as well as other firm-level characteristics related to wages.<sup>1</sup> Although not a focal point of their analysis, Lipsey and Sjöholm's (2004a, Tables 4-5) finding that SOE plants tended to pay higher wages than locally-owned private firms is of particular importance in this context. On the other hand, they did not test for spillovers from SOEs to private firms.

The peculiar nature of MNCs is a major reason that analysis of spillovers is usually focused on MNCs rather than on other ownership groups. MNCs are often distinguished from non-MNCs by analyzing what characteristics allow them to become multinationals in the first place. For example, many theorists (e.g., Dunning 1988, 1993; Hymer 1960; Markusen 1991) argue that MNCs' tendency to possess firm-specific assets, especially intangible assets related to production techniques and processes, marketing networks, and/or management ability, in relatively large amounts is a crucial distinguishing characteristic that allows a firm to become a multinational.<sup>2</sup> The possession of these assets is in turn thought to make MNCs more efficient than non-MNCs. A related trait is that MNCs also tend to be relatively technology- and human-capital-intensive compared to non-MNCs. MNCs thus tend to pay relatively high wages because they demand relatively skilled workers and because

---

<sup>1</sup> Lipsey and Sjöholm distinguish four types of labor by educational achievement and estimate separate equations for both white and blue collar workers. On the other hand, the aforementioned studies of Thailand, for example, are not able to distinguish labor by educational or skill level, though they are able to distinguish blue and white collar workers (Matsuoka-Movshuk and Movshuk 2006, Ramstetter 2004). Similarly regressions for Venezuela and Mexico are also in Aitken et al (1996) do not control for worker education levels.

<sup>2</sup> Other theorists (e.g., Buckley and Casson 1992; Casson 1987; Rugman 1980, 1985) dispute this view, asserting that internalization is the sole necessary condition for a firm to become a MNC, and that the possession of firm-specific assets is a sufficient but not a necessary condition for a firm to become a MNC. However, all agree that MNCs tend to possess these assets in relatively large amounts.

their workers are often more efficient than in non-MNCs which do not have access to the MNCs' intangible assets.

On the supply side, workers may be relatively reluctant to work for MNCs and demand a premium for working in a less familiar MNC environment. A related consideration is the fact that developing economies such as Vietnam, Indonesia, and Thailand often face limited supplies of the skilled workers that MNCs often seek to hire. As a result, labor turnover is often extremely high, especially for middle- or top-level managers and technical personnel, and MNCs may pay relatively high wages as a means of reducing turnover and related training and/or adaptation costs.<sup>3</sup> The findings of Lipsey and Sjöholm (2004a, 2004b, 2006) discussed above are particularly important in this context because they suggest that MNCs continue to pay a wage premium even after labor quality is controlled for in some detail. Although the influence of labor quality may not have been completely controlled for, the persistence of substantial wage differentials even after accounting for various levels of labor quality suggests that MNCs probably pay a premium above and beyond what is required to compensate for differences in labor quality.

In the Vietnamese case, it is also important to note that economic policies reinforce the tendency for MNCs to pay higher wages than private firms in particular (McCarty 1999, Brassard 2004). Perhaps the most important policies in this regard are those requiring MNCs and SOEs to pay relatively high minimum wages and provide more comprehensive access to social security and other

---

<sup>3</sup> In addition to explicit training costs, firms often incur implicit adaptation costs when labor turnover is high because it takes workers time to understand new jobs and perform them efficiently. Moreover these costs probably increase with the complexity of the job.

non-wage forms of compensation than private firms. Moreover, MNCs are often required to pay more compensation per employee than SOEs, and wholly-foreign MNCs must pay more than joint ventures involving MNCs. SOE wages are also largely controlled by the state and tend to be set above market levels for most workers.

In addition to being relatively efficient compared to non-MNCs, MNCs are often asserted to influence the performance of non-MNCs through several channels. For example, MNCs will often purchase inputs from local suppliers or subcontract certain production lines to local firms. Especially in developing countries such as Vietnam, the local supplier base is often relatively weak and the MNC must teach its local partners how to guarantee proper quality control, creating a technological spillover to the local firm involved. Labor mobility is a second avenue of spillovers from MNCs to local firms. As indicated above, labor mobility is often rather high in Southeast Asia's developing economies for example, especially among relatively skilled workers. Local firms can and do headhunt such talent from MNCs. One also hears stories of other MNC workers who quit an MNC to start up a locally-owned firm which produce goods and/or services which compete with MNC products and/or serve as inputs for their former MNC employers. The entry of MNCs can also increase the level of competition in a local market, forcing local firms to increase their efforts to become more efficient.

The empirical analysis of spillovers has generated varied results, with some researchers emphasizing the mixed evidence regarding such spillovers. For example, the review by Görg and Greenaway 2003, p. 7) emphasizes results of six studies for manufacturing industries in Venezuela,

Spain, the Czech Republic, Bulgaria, and Romania which suggest that productivity spillovers were negative in these economies. They also point to another 11 studies suggesting that productivity spillovers were statistically insignificant in a wide range of economies and emphasize that spillovers have generally been negative or negligible in transition economies such as Vietnam. On the other hand, there is growing evidence consistent with the existence of positive wage and productivity spillovers in Indonesia (e.g., Lipsey and Sjöholm 2004b, 2005, 2006; Takii 2006) and Thailand (Matsuoka-Movshuk and Movshuk 2006, Kohpaiboon 2006, Ramstetter 2006), though the evidence for Thailand is considerably weaker than evidence for Indonesia.<sup>4</sup>

Comparisons of SOEs and other firm types are considerably different than comparisons of MNCs and non-MNCs. Economists often emphasize that the primary difference between SOEs and non-SOEs is the existence of a relatively weak profit motive in SOEs. This in turn leads to expectations that SOE managers are less motivated to foster efficiency in their firm's operations than non-SOEs and that SOEs will thus tend to be more inefficient than non-SOEs. However, previous industry-level evidence from Vietnam's industrial survey of 1998 data suggests SOEs generally had higher labor productivity and wage levels than local plants but lower levels than MNCs (Phan and Ramstetter 2004, pp. 390-391). On the surface this evidence would appear to contradict expectations

---

<sup>4</sup> The reason the Thai evidence is considered to be weaker is because the results are obtained from simple cross sections which are more likely to have simultaneity problems, which result because MNCs may be attracted to high productivity or high wage industries. Fortunately we have panel data for Vietnam, which should make it easier to address the simultaneity problem by focusing on changes over time (fixed effects estimates). Note that Kohpaiboon's study also attempts to account for this simultaneity by using an instrumental variable estimator. However, it is often difficult to find appropriate instruments the use of panel data (which are not available for Thailand, but are available for Indonesia) is the more common method of reducing the risk of running into this problem.

that SOEs are relatively inefficient but there are several reasons to avoid jumping to conclusions on the basis of this evidence. First, this comparison of labor productivity and labor compensation does not account for any other influences on productivity or wage differentials. Second, it does not account for the influence of firm-level characteristics. Accounting for either of these (or other) factors could easily reverse this result.

On the other hand, the aforementioned finding of relatively high wages in Indonesia's SOEs is more difficult to explain away because the aforementioned influences are controlled for in some detail. Results from Vu (2003) which suggest that Vietnam's SOEs "recorded a rather high level of technical efficiency, as well as a moderate improvement in technical efficiency between 1997 and 1998" (p. 87) are also more difficult to reconcile with expectations that SOEs will generally be more inefficient than non-SOEs. Several surveys of the empirical literature (e.g., Aharoni 2000; Megginson and Netter 2001, and Stretton and Orchard 1994) also highlight a number of cases in which SOE do not appear to be less profitable and/or less efficient than private firms, while two of Northeast Asia's most efficient steel firms in the 1990s were a SOE (Taiwan's China Steel) and a former SOE which was recently privatized (Korea's Pohang Steel, Ramstetter and Movshuk 2005).

Thus, the extent to which SOEs are more or less efficient than non-SOEs would appear to be an empirical matter. Similarly, although we are unaware of any previous studies trying to evaluate the extent of spillovers from SOEs, it is interesting to see if SOE presence is correlated with wages in local private firms. This evaluation is of particular interest because Vietnamese policy makers have often emphasized how SOEs should play leading roles in industry and that private firms should seek

to cooperate with SOEs (Vu 2005, pp. 304-306).

### **3. Ownership Patterns, Compensation and Wage Differentials, and Related Indicators**

In January 2000, Vietnam implemented a new Enterprise Law that removed many of the legal and regulatory barriers previously faced by locally-owned private businesses.<sup>5</sup> Partially as a result of this change, employment of private manufacturing firms with positive employment, sales, labor compensation, and fixed assets more than doubled from between 2000 and 2004, to reach 15,363 in 2004.<sup>6</sup> About half of these private manufacturers were small, although the number of medium-large private firms with 20 or more employees increased even more rapidly, 2.3-fold to reach 7,743 in 2004. In contrast, the vast majority of MNCs (91-93 percent) and SOEs (98-99 percent) in manufacturing were medium-large firms. Their numbers were much smaller but the number of medium-large manufacturing MNCs increased rapidly in 2000-2004 (2.2-fold to 2,092 in the latter year), while the number of medium-large manufacturing SOEs declined (20 percent to 1,229 in the latter year). In the following analyses, we focus on comparisons among medium-large firms because comparisons among ownership groups are likely to be distorted if smaller, predominately private firms are included.<sup>7</sup>

---

<sup>5</sup> See Phan and Ramstetter (2007, pp. 3-8) for details on the Vietnam's Enterprise Law and related reforms.

<sup>6</sup> See Appendix Tables 8a-8h for details on the number of firms, including comparisons with official compilations. These data are compilations General Statistics Office (various years b) and differ from official compilations (General Statistics Office, various years a) primarily because we dropped some duplicates (see Ramstetter and Phan 2007, Appendix A) and firms reporting zero employment, sales, labor compensation, and fixed assets. In addition, our data sets may not be identical to those used when compiling official publications, though we have no way of verifying this.

<sup>7</sup> Although we have also obtained data for 2005 and present them in the Appendix Tables as

The decline in the number of SOEs reflects efforts to privatize and consolidate a number of SOEs, but employment and sales continued to grow among SOEs in 2000-2004 (Table 1). The growth of employment was very slow (6 percent) but sales increased much more rapidly (88 percent). However, SOE shares of total employment (46 percent in 2000 and 27 percent in 2004) and total sales (40 and 29 percent, respectively) both fell markedly. Correspondingly, employment and sales both grew much more rapidly in private firms (2.3- and 3.9-fold, respectively) and their shares of both activities grew substantially (from 31 to 38 percent of employment and from 17 to 27 percent of sales). MNC shares of employment also increased rapidly (from 23 to 34 percent, respectively) but MNC shares of sales changed very little (from 43 to 44 percent).

There is a very large variation in ownership shares among manufacturing industries, but a similar trend toward decreased shares of SOEs and increased shares of private firms and MNCs is observed. For example, SOEs accounted two-fifths of total employment or more in 16 of the 27 industries listed in Table 1 in 2000, but in only nine industries in 2004. Moreover, SOE employment shares fell by 10 percentage points or more in 18 of the 27 industries as the trend toward lower SOE shares was widespread. Meanwhile, employment shares exceeded two-fifths in eight industries for private firms in 2000 and nine industries in 2004, while employment shares increased more than 10 percentage points in 11 industries. MNC shares were also larger than two-fifths in six industries in

---

available, we limit detailed comparisons to 2000, 2002, and 2004, primarily because important variables on the number of science and technology workers are only available for these years. In addition, this section focuses on data for 2000 and 2004 to conserve space, though the regression analysis in the following section will also consider 2002. Please also note that we obtained the 2005 data before official compilations became available and our version of the 2005 data has far more duplicates and apparent errors than data for other years (see Ramstetter and Phan 2007, Appendix A).

2000 and eight in 2004, while there were 10 industries in which MNC shares increased more than 10 percentage points.

In 2004, SOEs had large employment shares of two-fifths or more in four so-called key industries (chemicals, non-metallic mineral products, basic metals, and general machinery), three other industries in which state interests are often high (e.g., beverages [including alcohol], tobacco, and publishing), and two others (textiles and rubber; calculated from Table 1). As often observed in Asian economies, MNC shares were high in five machinery industries (office and computing machinery, electrical machinery, radio, television, and communication machinery, precision machinery, motor vehicles) where MNCs are thought to possess firm-specific assets that give them competitive advantages. MNC shares were also high in five other industries using more standardized technologies (apparel, leather, footwear, furniture, and miscellaneous manufacturing). Private shares were then in food, wood, paper, petroleum products, plastics, non-metallic mineral products, fabricated metals, furniture, and recycling.<sup>8</sup>

In addition to the large changes in ownership structure, simple calculations suggest large changes in wage differentials among ownership between 2000 and 2004. For example, in 2000, if the mean total compensation per worker is calculated for all manufacturing firms, MNCs paid by far the

---

<sup>8</sup> As reflected in the aggregate shares cited above, MNC shares of industry sales were large in a much larger number of industries (16 in both 2000 and 2004), while shares of SOEs and private shares were large in fewer industries (11 in 2000 and five in 2004 for SOEs, three in 2000 and seven in 2004). However, similar to trends in employment shares, private shares of industry sales increased more than 10 percent points in a relatively large number of industries (8) while SOE shares also fell more than 10 percent points in many industries (10).

most, 173 more than private firms and 95 percent more than SOEs (Table 2).<sup>9</sup> However, by 2004 these compensation differentials fell markedly to 92 percent and 22 percent, respectively. On the other hand, the differential between SOEs and private firms increased slightly from 40 percent to 57 percent. Wage payments accounted for the vast majority of total compensation, but non-wage compensation was higher in SOEs (4 percent in both years) than in private firms (1-2 percent) and MNCs (2 percent). However, the size of non-wage compensation was small and wage differentials were not substantially different from compensation differentials when all manufacturing firms are averaged.<sup>10</sup> This pattern is fairly consistent across industries as well; wages never accounted for less than 91 percent of total compensation in private firms, 93 percent in SOEs, and 95 percent in MNCs in the 27 industries listed in Table 2.

There was a much larger variation in compensation and wage differentials across industries, however. For example, MNC-private compensation differentials ranged from 49 to 895 percent in 2000 and from 19 to 948 percent in 2004 (Table 2). There was less pronounced but still substantial variation across industries for other (MNC-SOE and SOE-private) differentials as well.<sup>11</sup> Despite this variation, there was still a very strong tendency for total compensation and wages to be highest in MNCs, followed by SOEs, and then private firms, and for these differentials to diminish over time.

---

<sup>9</sup> Table 2 contains data on both total compensation and wages per worker. The analytical focus in this paper is on the more comprehensive measure of total compensation.

<sup>10</sup> For wages, MNC-SOE differentials were slightly larger (99 percent in 2000 and 25 percent and 2004) while SOE-private differentials were slightly smaller (36 and 53 percent, respectively) and MNC-SOE differentials were almost identical (172 percent and 91 percent, respectively).

<sup>11</sup> MNC-SOE differentials varied between -7 and 213 percent in 2000 and between -26 and 309 percent in 2004, while SOE-private differentials varied between -10 and 338 percent in 2000 and between -16 and 221 percent in 2004.

There was no industry in which MNCs paid lower compensation than private firms and MNC-private differentials were 100 percent or larger in 20 of 25 industries for which comparisons were possible in 2000 and 9 of 26 in 2004. MNCs also paid higher compensation than SOEs in the vast majority of industries (23 of 24 in 2000 and 19 of 25 in 2004) and MNC-SOE differentials were 50 percent or larger in three-fourths of the industries (18) in 2000 but only one-third (8) in 2004. Meanwhile, SOE-private differentials were also positive in the vast majority of industries and the number of industries with differentials of 50 percent or larger increased from one-fourth of 24 industries in 2000 to 48 percent of 25 industries in 2004.

Thus both the industry-level data and the aggregate data suggest that (1) MNCs pay the highest compensation and differentials between MNCs and other firms (private firms or SOEs) have diminished over time and (2) SOEs also pay more than private firms but SOE-private differentials have widened somewhat. However, these simple comparisons ignore the fact that other firm characteristics such as capital intensity, size, and labor quality can affect wage differentials. For example, there was a very strong tendency for MNCs to use more fixed assets per worker than private firms or SOEs. By this measure, capital intensity for MNCs was on average 10 times higher than private firms in 2000 and 6.6 times higher than SOEs (Table 3). Similar to trends in wage differentials, these capital intensity differentials fell over time to 4.3 times and 2.2 times, respectively, in 2004. In contrast, SOE-private differentials increased some, from 1.5 times to 2.0 times. As with compensation per worker there was also wide inter-industry variation in capital intensity, but there the strong tendency to be more for MNCs to be the most capital intensive, followed by SOEs, is also

observed among the industries listed in Table 3.<sup>12</sup> As might be expected similar patterns were also observed in sales per worker.<sup>13</sup>

SOEs and MNCs were also much larger than private firms, even when comparisons are limited to medium-large firms. Size differentials increased some over time as employment per firm increased in SOEs and MNCs but declined slightly in private firms (Table 3). As a result, SOE-private size differentials rose from an average of 3.3 to 4.4 and MNC-private differentials increased from 2.6 to 3.3. Meanwhile, SOE-MNC differentials fell slightly on average from 0.8 to 0.7. Here again large SOE-private and MNC-private differentials were common despite a wide variation in size differentials across industries. For example, SOEs were 2 times or more larger than private firms in 21 of 24 industries in 2000 and 22 of 25 in 2004, while MNC-private differentials were 2 times or more in 17 of 25 industries in 2000 and 23 of 26 in 2004. MNCs were also smaller than SOEs in 19 of 24 industries in 2000 and 19 of 25 in 2004.

The only measures of labor quality that are available suggest somewhat more varied patterns, however (Table 4). For example, shares of science and technology workers in total employment were largest for MNCs in 2000 (15 percent), followed by SOEs (11 percent) and private firms (6.0

---

<sup>12</sup> For example, capital intensity was two times or more the level in private firms in 24 of 25 industries in 2000 and 24 of 26 in 2004. MNC-SOE differentials were also 2 times or more in 22 of 24 and 17 of 25 industries, respectively. SOEs had higher capital intensity than private firms in 17 of 24 and 21 of 24 industries, respectively.

<sup>13</sup> Differentials in sales per worker were smaller, however, declining from an average of 3.1 times to 2.4 times for MNC-private differentials and from 3.2 times to 1.8 times for MNC-SOE differentials, while SOE-private differentials increased from 1.0 to 1.3 times (Appendix Tables 3v, 3w, 3x). Sales (including both purchases of intermediate goods and value added) per worker is generally considered and a poorer measure of labor productivity than value added per worker, but value added data are not available in this data set.

percent), but SOEs had the largest share in 2004 (13 percent), followed by MNCs (11 percent), and private firms (6.7 percent). The share of female workers in the total was also highest in MNCs in both years (46 percent in 2000 and 51 percent in 2004). This suggests lower worker quality in MNCs because female workers are often less educated or trained than their male counterparts. There is also a tendency to pay female workers less than their male counterparts even after these differences are accounted for (Liu 2004).

#### **4. Compensation Differentials after Accounting for Firm and Industry Characteristics**

As indicated toward the end of the previous section, compensation or wage differentials can result from related differences in firm characteristics such capital intensity and size, in addition to labor quality. In this section, the focus is thus on estimating total compensation equations that account for these related factors. In addition, the effects of producer concentration on compensation differentials are investigated by adding either the 4-firm concentration ratio or the Herfindahl index for 25 of the 27 industries listed in Tables 1-4 to compensation equations.<sup>14</sup> Other industry-specific effects are first accounted for by including intercept dummies for seven of eight industry groups. These groups are defined to include industries in which multi-product firms are likely to compete with other firms in the same group.<sup>15</sup> Coefficients on dummy variables for MNCs and SOEs then

---

<sup>14</sup> Two industries, printing and publishing and petroleum products were omitted from the regression analysis because they have special characteristics that make them very different from the other manufacturing industries studied. Because the concentration variables are defined using a more detailed industrial classification than industry dummies (see note 15 below) it is possible that the coefficients on the concentration variables may also pick up other industry-related effects.

<sup>15</sup> The eight groups are (1) food, beverages, and tobacco, (2) textiles, apparel, leather, and footwear,

reveal whether any ownership-related compensation differentials remain after accounting for these various firm- and industry-group characteristics. The basic equations to be estimated are thus as follows:

- $$(1) \ln(CE_{ij}) = a0 + a1[\ln(KE_{ij})] + a2[\ln(E_{ij})] + a3(ES_{ij}) + a4(EF_{ij}) + a5(DS_{ij}) + a6(DM_{ij}) + a7(C4_j) + a8(\mathbf{DI}_k)$$
- $$(2) \ln(CE_{ij}) = b0 + b1[\ln(KE_{ij})] + b2[\ln(E_{ij})] + b3(ES_{ij}) + b4(EF_{ij}) + b5(DS_{ij}) + b6(DM_{ij}) + b7(HF_j) + b8(\mathbf{DI}_k)$$

where

$C4_j$ =4-firm concentration ratio of industry j (percent)

$CE_{ij}$ =compensation per employee in firm i of industry j (million dong, 2000 prices)

$\mathbf{DI}_k$ =a vector of dummy variables for industry group k

$DM_{ij}$ =dummy variable for MNC firm i in industry j

$DS_{ij}$ =dummy variable for SOE firm i in industry j

$E_{ij}$ =firm size, measured as the number of employees in firm i of industry j

$EF_{ij}$ =share of female workers in total employment of firm i of industry j (percent)

$ES_{ij}$ =share of science and technology workers in total employment of firm i of industry j (percent)

$HF_j$ =Herfindahl index for industry j (percent)

$KE_{ij}$ =fixed assets per employee in firm i, industry j (million dong, 2000 prices)

The coefficients on capital intensity ( $a1$  or  $b1$ ), firm size ( $a2$  or  $b2$ ), and the share of science and technology workers ( $a3$  or  $b3$ ) are expected to be positive as these variables reflect higher labor productivity or greater use of highly skilled labor. In contrast, the sign of the coefficient on the share of female workers ( $a4$  or  $b4$ ) is likely to be negative because female workers are likely to have less training than their male counterparts and because previous studies suggest discrimination in favor of

(3) wood, paper, and furniture, (4) chemicals, rubber, and plastics, (5) non-metallic mineral products, basic metals, and metal products, (6) machinery (general machinery, office and computing machinery, electrical machinery, radio, television & communication machinery, and precision machinery), (7) motor vehicles and other transportation equipment, and (8) miscellaneous manufacturing and recycling (the control group). Industry dummies are often defined in greater detail but this is impossible here because the concentration variables are generally defined at the 2-digit level (4 of the 23 2-digit categories are disaggregated into two components each to make a total of 27 industries) of Vietnam's Standard Industry Classification (VSIC) as in Tables 1-4. More detailed definitions of industry dummies (e.g., the 3-digit classification) were also tried but did not work because of excessively high correlations with the concentration variables.

male workers. The sign of the coefficient on the concentration variable ( $a7$  or  $b7$ ) should be positive to the extent that marginal value product of labor is higher in highly concentrated industries than in less concentrated ones, but many other factors such as competition in labor markets and labor mobility among industries may overwhelm this factor. The sign of this coefficient is thus indeterminate *a priori*. Finally, if SOEs and MNCs pay a wage premium after accounting for these factors as expected, signs of coefficients on dummy variables for SOEs and MNCs ( $a5$  or  $b5$  and  $a6$  or  $b6$ ) should be positive and significant.

Although equations (1) and (2) some of the differences among industry groups, it is also likely that they impose an unrealistic assumption that all slope coefficients are equal for all industry groups. One way to relax this assumption is to estimate the following equations for the eight industry groups identified by dummy variables in equations (1) and (2), as follows:

$$(3) \ln(CE_{ij}) = c0 + c1[\ln(KE_{ij})] + c2[\ln(E_{ij})] + c3(ES_{ij}) + c4(EF_{ij}) + c5(DS_{ij}) + c6(DM_{ij}) + c7(C4_j)$$

$$(4) \ln(CE_{ij}) = d0 + d1[\ln(KE_{ij})] + d2[\ln(E_{ij})] + d3(ES_{ij}) + d4(EF_{ij}) + d5(DS_{ij}) + d6(DM_{ij}) + d7(HF_j)$$

where all variables are defined as in equations (1) and (2) above.

Although estimation of equations (3) and (4) is expected to reveal some substantial differences in coefficient values among industry groups, the expected signs of corresponding coefficients are the same as in equations (1) and (2).

Equations (1) to (2) are best estimated in simple cross sections for 2000, 2002, 2004 and the coefficients on the ownership and concentration variables, as well as samples sizes and goodness-of-fit measures, are reported in Table 5.<sup>16</sup> Although cross section estimates fail to take

---

<sup>16</sup> Estimation is limited to these three years because data on scientific and technological workers is not available for other years.

advantage of the panel properties of these data, they provide the most reliable estimates of wage differentials obtainable from the available data and are best suited to answer the question of which type of firm pays relatively high compensation at a given point in time.<sup>17</sup>

The major results of these estimates are generally in line with the expectations outlined above (Table 5). Coefficients on capital intensity, size, and the share of science and technology workers were positive, while coefficients on the female share of employment were negative in all equations for all of the samples examined (see Appendix Tables 5a, 5b for these details). Moreover, as noted in Table 5, these coefficients were almost always highly significant at the 1 percent level or better. The only exceptions were in the motor vehicles and other transportation equipment group, where all coefficients were still significant at the standard 5 percent level or better, and in the small heterogeneous group of miscellaneous manufacturing and recycling, where coefficients on the share of science and technology workers in 2002 and on size in 2004 were not significant at standard levels. R-squared varied between a minimum of 0.13 and a maximum of 0.44, which is typical for large cross sections such as these, and F-tests always reject the null that slope coefficients are zero at the 1 percent level or better. Thus, cross section estimates of equations (1) to (4) appear to be useful for

---

<sup>17</sup> It is also possible and potentially interesting to estimate equations (1) to (4) in three panels for 2000-2002, 2002-2004, and 2000-2002-2004, and attempts were made to do this. However, it is impossible to obtain meaningful fixed effects estimates in this case because relatively few (124) firms changed ownership between 2000 and 2002 or between 2002 and 2004. Moreover, of these firms, only two were MNCs, one which changed from being an MNC in 2000 to a private firm in 2002 and then changed back to an MNC in 2004, and another which changed from being an MNC in 2000 to a private firm in 2002 and 2004. Correspondingly, it is impossible to conduct meaningful Hausman tests of whether fixed effects or random effects specifications are best when equations include the MNC dummy and the program used (Stata v9) failed to estimate the coefficient on the MNC dummy in almost all of the industry group samples examined.

examining compensation differentials and the effect of producer concentration on compensation.

The most conspicuous result emerging from Table 5 suggests that MNCs do indeed pay higher compensation even after accounting for related firm-level characteristics, as well as differences among industry groups. Coefficients on the MNC dummy are positive and highly significant (at the 1 percent level or better) in all equations and samples for which estimates are performed. The estimates of this coefficient (and most others) are also very similar regardless of the concentration measure used but they do vary over time and among industry groups. In the equation for all manufacturing, for example, the coefficient on the MNC dummy declined from 0.49-0.50 in 2000 to 0.44 in 2002 and 0.38 in 2004. There was a wide variation across industries, however, with relatively large differentials (minimum of 0.40 or more) in food, etc., chemicals, etc., non-metallic mineral products, etc., machinery, and motor vehicles, etc., and relatively small differentials (maximum of 0.30 or less) in textiles, etc., and wood, etc. In addition, differentials tended to be largest in 2002, not 2004, when estimating equations for the eight industry-groups and variation over time was relatively small. For example the averages of coefficients from these groups varied between 0.42 and 0.46 if unweighted and between 0.39 and 0.42 if weighted by the number of observations in each sample. All of these differentials are much smaller than corresponding differentials in Table 2, however. This suggests that a large part of those differentials are indeed related to firm-level characteristics and labor quality. It also suggests that use of more complete measures of labor quality might further reduce the differentials observed. The results also suggest that large declines in compensation differentials observed between 2000 and 2004 in Table 2 and the smaller declines observed in the estimates for

manufacturing firms combined largely disappear if differences among industry groups are accounted for.

The regression results also contrast sharply with the data in Table 2 by suggesting that SOE-private differentials were negative and significant at standard levels in many cases. For example, in the estimates for all manufacturing combined, the SOE-private differential was -0.10 in 2000, negligible (insignificant) in 2002, and 0.06 in 2004. When estimates for industry groups were performed and years the coefficient on the SOE dummy was negative and significant in 16 of the 54 samples examined but positive and significant in another. Negative differentials were common in food., etc. (2002 and 2004), textiles, etc. (all years), and wood, etc. (2000 and 2002) while positive differentials were often observed in chemicals, etc. (all years), machinery (2002 and 2004), and motor vehicles, etc. (all years). However, even at the industry level SOE-private differentials varied more over time than MNC-private differentials. Thus, the regression analysis suggests that large portions of the SOE-private compensation differentials observed in Table 2, resulted from the fact that SOEs had other characteristics leading to relatively high compensation such as relatively high capital intensity and large size, and that these characteristics were so overwhelming as to result in negative differentials once they were accounted for.

The coefficients on producer concentration were often insignificant at standard levels suggesting little relationship between these measures of competition and compensation levels. In the equation for all manufacturing, for example, the coefficient on the 4-firm concentration ratio was positive and significant in both 2000 and 2004 and the coefficient on the Herfindahl index was

significant in 2004, but others were not significant. However, results from industry groups again differ markedly, with food, etc. (2000 and 2002) being the only group for which higher concentration had a significant and positive effect on compensation. In contrast the relationship between producer concentration and compensation was always negative in three of the industry groups examined (textiles, etc., wood, etc., and motor vehicles, etc.), as well as in 5 of 6 samples for non-metallic mineral products, etc. (all years for the Herfindahl, 2000 and 2002 for the 4-firm concentration ratio).

## **5. Compensation Spillovers to Private Firms**

In addition to paying higher wages than their local counterparts, MNCs are also thought to influence compensation and wage levels in local plants through spillovers as described above. Also as described above, SOEs are purported to play a leading role in Vietnamese industry so it is interesting to see if evidence is consistent with the existence of similar spillovers originating in SOEs as well. The extent of compensation spillovers to private firms is thus examined by estimating equations similar to (1) and (2) in samples of private firms, and then including SOE and MNC shares of industry employment as independent variables in equations (5) to (8) below:

$$(5) \ln(CE_{ij}) = e0 + e1[\ln(KE_{ij})] + e2[\ln(E_{ij})] + e3(ES_{ij}) + e4(EF_{ij}) + e5(SSH_j) + e6(MSH_j) + e7(C4_j) + e8(DI_k)$$

$$(6) \ln(CE_{ij}) = f0 + f1[\ln(KE_{ij})] + f2[\ln(E_{ij})] + f3(ES_{ij}) + f4(EF_{ij}) + f5(SSH_j) + f6(MSH_j) + f7(HF_j) + f8(DI_k)$$

where

$MSH_j$ =the MNC share in the employment of industry j (percent)

$SSH_j$ =the SOE share in the employment of industry j (percent)

all other variables as defined in equations (1)-(2) above

Following the usual practice, these equations are estimated in samples of all manufacturing industries

and equations similar to (3) and (4) are not estimated here. This failure to account for inter-industry-group in variation in spillover effects is one of the limits imposed by the commonly used methodology but there is no practical alternative we are aware of. Signs on the basic controls (capital intensity, size, the share of science and technology workers, the share of female workers are expected to be the same as in the estimates of equations (1) to (4). If coefficients on the MNC or SOE shares are positive, they are then interpreted as evidence that greater MNC or SOE presence in an industry leads to higher compensation in private firms in that industry, or positive compensation spillovers. Such spillovers may also be negative.

Cross section results (Table 6) suggest that spillovers from MNCs and SOEs were both negligible (insignificant) in 2000, but positive and significant in 2002 and 2004. Although coefficients on all control variables were of the expected sign and highly significant at the 1 percent level or better, the explanatory power of these equations, which are estimated for private firms only, was quite a bit lower than for the wage-differential equations which were estimated in samples including MNCs and SOEs and described in the previous section (Appendix Table 6). Although these results may seem like reasonable descriptions of the relationship between wages in local firms and SOE or MNC presence at a given point in time, there is a potential for simultaneity to result in inconsistent estimates because MNCs and SOEs may be attracted to high wage industries.

Fixed effects panel estimates (Table 7) measure how private firm compensation changes over time after controlling for so-called unobserved firm-specific characteristics, in addition to the observable characteristics specified in equations (5) and (6). In many ways, these panel estimates are

more appropriate for examining spillovers, because they focus more on the question of whether larger MNC or SOE presence leads to increases or decreases of compensation in private firms over time rather than on the cross section question of whether compensation in private firms is related to the size of MNC or SOE presence. By focusing on changes in wages rather wage levels, they are also less likely to be affected by simultaneity.

Given the different focus of the questions posed by fixed effects estimates, it is perhaps not surprising that fixed effects results differ from the cross section results in several respects.<sup>18</sup> First, of the coefficients on the four control variables, only the capital intensity coefficient is consistently significant at standard levels (5 percent or better) and these coefficients are positive as expected. Coefficients on the share of scientific and technological workers are also positive and significant at standard levels for 3-year sample and weakly significant at the 10 percent level or better for the 2002-2004 sample, but is insignificant in the 2000-2002 sample. Coefficients on size and the female share are never significant and often have signs that contradict expectations. Second, the MNC share coefficient is never significant at standard levels and is weakly significant in only one of the equations in the 3-year sample. Thus, these estimates suggest compensations spillovers from MNCs were not very strong. Third, on the other hand, the SOE share coefficients are highly significant in all specifications, but they are negative, suggesting larger SOE presence leads to lower compensation in private firms. Fourth, coefficients on the concentration variable are highly significant and negative in

---

<sup>18</sup> Random effects models were also estimated and Hausman tests performed to get an indication of which specification was more appropriate. These tests all indicate that the fixed effects formulation should be preferred.

two of the three samples (2002-2004 and the 3-year sample), indicating that private firms pay more in less concentrated industries, at least in recent years.

The major results obtained from panel estimates thus contrast starkly with the cross section results. This is perhaps not surprising given the differences in the questions posed by the two modes of analysis but there are also a large number of potential problems in the panel analysis that do not exist in the cross sections. Perhaps the largest problem results from the fact that a number of firms entered manufacturing or changed industries in Vietnamese manufacturing over this period (Phan and Ramstetter 2007). Thus, panels covering even a short two-year period become highly unbalanced which complicates estimation and interpretation. Second, to facilitate panel estimates, fixed assets and compensation were both deflated using sector-specific producer price indices, but classifications used in the producer price data and the firm data do not match exactly and it is not clear that this is the best index to deflate these variables.<sup>19</sup> Third, there are potentially important problems with the firm codes in these data, which can make the panels one can create of limited reliability. For example, there were several apparent duplicates and many of the duplicate entries apparently referred to different branches of the same firm (Ramstetter and Phan 2007, Appendix). On the other hand, both the cross sections and the panels have potential simultaneity problems, and these problems are potentially more severe in the cross sections. Dealing with such problems is a major task for future research but is quite complicated when using these data sets.<sup>20</sup>

---

<sup>19</sup> For labor compensation, one might arguably prefer to use the consumer price index as a deflator, but this would imply a high degree of inter-industry labor mobility that may be unrealistic. For fixed assets, one would clearly prefer a capital goods deflator but this is not available.

<sup>20</sup> The major problem is the inability to identify proper instruments. The inability to identify such

## **6. Conclusion**

The results of this paper first suggest that both MNCs and SOEs paid their workers higher wages and total compensation than private firms. If other related firm- and industry-level characteristics are not controlled for, MNC-private differentials were largest but declined over time while SOE-private differentials were smaller but increased over time. Second, more rigorous analysis suggests that compensation differentials were much smaller after controlling for a number of related firm- and industry-level characteristics. Indeed, the influence of related factors was so large that SOE-private differentials were negative in 2000 after the controls were considered, but they were significantly positive in the 2004 sample. Likewise MNC-private differentials were always significantly positive and declined somewhat overtime, though considering the controls suggests the rate of decline was slower than indicated by descriptive statistics. Third, estimates for all manufacturing suggest that producer concentration was positively related to compensation levels, but that this relationship was not always significant depending on the year or measure of concentration used. Fourth, more detailed analysis suggests that the results regarding SOE-private differentials varied greatly among industry groups while the effects of producer concentration on compensation levels were actually negative in about half of the industry-groups and rarely positive. MNC-private differentials also differed greatly across industries, although they were positive and significant in all industry-groups. The results regarding MNC-private differentials are thus consistent with evidence from previous studies of other Southeast Asian economies and with expectations created by

---

instruments is a major reason that most previous studies of wage differentials have usually relied on single-equation estimation techniques.

Vietnam's policy of requiring MNCs and SOEs to pay relatively high wages. On the other hand, the results regarding SOE-private differentials are perhaps surprising because they suggest that SOEs often do not pay relatively high wages once controls such as capital intensity or firm size are considered.

The paper also examined the possibility that SOEs and MNCs generated spillovers that affected compensation levels in Vietnam's rapidly growing private sector. The first attempt was made in simple cross sections and suggested little effect of SOE or MNC presence on local firm compensation in 2000, but that larger SOE and MNC presence both led to higher compensation in private firms in 2002 and 2004. On the other hand, fixed effects panel estimates suggested that MNC presence did not have a strong effect on changes in private firm compensation during the period studied. Moreover, the fixed effects evidence suggests that increases in private firm compensation tended to be relatively low in industries with large SOE presence or high producer concentration. This in turn suggests that further efforts to spur competition and privatization of SOEs are likely to result in relatively rapid growth of worker incomes in Vietnamese manufacturing.

Note: see Appendix Tables 5a (Equations (1) and (2) for manufacturing) and 5b (equations (3) and (4) for industry groups) for coefficients on other independent variables and F-tests of the hypothesis that all coefficients are zero; coefficients on the four other independent variables were of the expected signs and significant at the 1 percent level or better in almost all of the 54 samples; exceptions were in motor vehicles and other transportation equipment (significant at 5 percent or better in all samples) and miscellaneous manufacturing and recycling (significant at 5 percent or better except for science and technology worker share in 2002 and size in 2004); all tests were conducted using heteroskedasticity-consistent standard errors; F-tests rejected the null of zero slopes at the 1 percent level or better in all 54 samples

Appendix Table 10: Wholesale Price Data and Concordance to Industrial Classification for Firm Data (2000=1)

VSIC code, Firm-level Classification	Wholesale Price Index Classification	2000	2002	2004
151 to 154-Food products	Food and beverage	1.000	1.022	1.079
155-Beverages	Food and beverage	1.000	1.022	1.079
16-Tobacco	Tobaccos	1.000	0.996	0.998
17-Textiles	Textile products	1.000	1.035	1.154
18-Apparel	Garment	1.000	1.177	0.902
191-Leather	Leather, articles of leather	1.000	1.047	1.078
192-Footwear	Leather, articles of leather	1.000	1.047	1.078
20-Wood products	Wood, banjo, species of bamboo	1.000	1.078	1.309
21-Paper	Paper and paper products	1.000	1.334	1.404
22-Publishing	Printing, record tapes and disks	1.000	0.980	1.041
23-Petroleum products	Crude oil, natural gas	1.000	0.908	1.747
24-Chemicals	Chemical products	1.000	1.056	1.237
251-Rubber products	Rubber, plastic products	1.000	1.094	1.307
252-Plastics	Rubber, plastic products	1.000	1.094	1.307
26-Non-metallic mineral products	Non metal products	1.000	1.023	1.222
27-Basic metals	Other metal	1.000	1.089	1.302
28-Fabricated metals	Metal articles	1.000	0.944	0.943
29-General machinery	Mechinery and equipment	1.000	0.928	1.200
30-Office & computing machinery	Mechinery, other equipment	1.000	1.022	1.229
31-Electrical machinery	Manufacture of radio & communication equipment & apparatus	1.000	1.039	1.074
32-Radio, television & communication	Manufacture of radio & communication equipment & apparatus	1.000	1.039	1.074
33-Precision machinery	Manufacture of radio & communication equipment & apparatus	1.000	1.039	1.074
34-Motor vehicles	Trailer and motor vehicles	1.000	0.963	0.979
35-Other transport equipment	Other transport means	1.000	0.971	1.059
361-Furniture	Wardrobe, table, chair	1.000	1.083	1.226
36 less 361-Miscellaneous manufact.	Wardrobe, table, chair	1.000	1.083	1.226
37-Recycling	Wardrobe, table, chair	1.000	1.083	1.226
